APRS GENERIC DIGIPEATING SATELLITES
for HT and MOBILE Satellite Communications

Bob Bruninga, WB4APR

It's time for mobile and handheld amateur satellite communications and we can do it easily. Proposals for amateur satellite constellations have been made in the past, but they assume a coordinated effort. Such an effort is unrealistic in the amateur environment. This paper suggests that the future growth of amateur satellites can accommodate uncoordinated growth and still provide synergistic advantages to mobile and handheld operations. There are several factors driving this concept making it easier, cheaper and more viable:

- Launches are plentiful, many free rides exist
- Electronics can be smaller than a softball
- The link from a handheld can be done with 1 watt
- Dual band HT's are plentiful
- Mobiles are a convenient time to operate for many
- Travelers need satellite comms in remote areas
- HT/mobiles need little coax, no preamps, nor complex antennas
- Mobiles/Handhelds provide a common user configuration
- HT/omni downlinks are ideal for school demonstrations
- Many Schools want to build satellites for education
- Amateur Satellites should not compete with the free bandwidth of the internet for fixed stations. We should concentrate some of our satellite bandwidth on amateur communications for mobiles and handhelds.

In the past, HAMS were the driving force behind each of our satellites wanting to do something new and different and better for AM radio. More bandwidth, higher speeds, new digital techniques, longer ranges. The justification for a new experiment provided the rationale for the project. With that mindset, there were lots of new things to tinker with but little support or peer justification for flying just another one-of-the-same.

The current climate is quite different. Universities want to build satellites for the education of their students. There are at least a dozen such satellites currently under construction. In this case it is the "design and building" that are the main educational drivers. This means some of these projects are actually looking for a mission, or an excuse to build a satellite. These satellites become "amateur" satellites simply because the spectrum is easy to get. We, "the AMSAT community" should provide guidance so that we get what we want and need for the future of amateur radio while these projects with deep pockets get the educational experience they need.

THE GENERAL MISSION AND BUILDERS CHANNEL:

What we need is a published General Mission requirement and a Builders Channel. This will encourage builders to consider the inclusion of a general purpose FM or digital transponder on a common channel. The resulting simple transponders would all be similar and provide the amateur community with a fleet of general purpose relays for mobile and handheld communications while providing builders with a persistent mission requirement. Actually there are three missions and three builders channels, one for FM voice, one for brief 1200 baud digital position/status/message uplinks and one for bulk downlink of all amateur traffic using the very efficient PACSAT protocol at 9600 baud.

Focusing builders-in-search-of-a-mission on this General Mission and Builders Channel with only one power-class of users (mobiles and HT's) will make much more efficient use of our precious spectrum and also keep the remaining spectrum available for other analog, wide band and experimental modes.

HT and MOBILE STATION CLASS:

Even though HT's and mobiles differ in power by 10 dB (5 versus 50 watts), they are comparable in most respects. The downlink is identical. Both use omni receive antennas with no cable loss. The uplink is also quite comparable. HT's can easily vary their orientation and polarity and/or use small antennas.

The popularity of AO-27 is matched only by its own congestion. Imagine, however, if there were 12 other AO-27's on the same frequency giving two passes per hour round the clock *AND* a change in operating habits to let everyone have a chance. Photo by Phillip Fortenberry, N5PF at last year's AMSAT Conference.
Thus the minutes. This is where everyone when over the USA, the distribution of smaller real-time messages to all users usually in receive only mode. At 9600 baud, that is a tremendous asset for amateur radio. By using 2 meters, the lower path loss means that stations need not track the satellite. Just leave their packet capable HT on the 9600 baud channel and it will receive the traffic whenever a bird flies over even if they are in receive only mode.

Further, this PACSAT protocol downlink can be REGION specific by not putting the file system on orbit, but on the ground! The 9600 baud channel simply operates in bent-pipe mode for major internet linked file servers on the ground. Thus when over the USA, the channel is full of traffic for USA mobiles. While it is over Europe, the bird is supplying all European traffic. Thus, the channel can be optimized for each region. This greatly multiplies overall worldwide capacity.

Since each satellite is only serving as the on-orbit digipeater for regional message servers, each satellite is generic, which means that via one's HT, that at any time serves to deliver the messages to all mobile handhelds within 1500 miles. The Regional Message Server ground station continuously transmits a stream of all message traffic. New messages are initially repeated more often than older messages on a decaying schedule. For example:

New messages are repeated every 2 minutes
- After 30 minutes every 3 minutes
- After 60 minutes every 4 minutes
- After 2 hours every 5 minutes
- After 4 hours every 6 minutes
- After 8 hours every 7 minutes
- After 16 hours every 8 minutes
- After 24 hours every 9 minutes

Thus, at 9600 baud and an average message length of 1K, over 500 messages per pass per satellite can be delivered. Yes, it makes the satellite less valuable over the oceans and most of the 3rd world, but those areas are aptly covered by the existing Pacsats that cannot deliver traffic to handhelds.

The objective of this channel is not to replace the existing PACSAT store-and-forward message/file systems, but to augment them for the downlink distribution of smaller real-time messages to all users usually in receive only mode. At 9600 baud, that is a tremendous asset for amateur radio. By using 2 meters, the lower path loss means that stations need not track the satellite. Just leave their packet capable HT on the 9600 baud channel and it will receive the traffic whenever a bird flies over even if they are in receive only mode.

Further, this PACSAT protocol downlink can be REGION specific by not putting the file system on orbit, but on the ground! The 9600 baud channel simply operates in bent-pipe mode for major internet linked file servers on the ground. Thus when over the USA, the channel is full of traffic for USA mobiles. While it is over Europe, the bird is supplying all European traffic. Thus, the channel can be optimized for each region. This greatly multiplies overall worldwide capacity.

Since each satellite is only serving as the on-orbit digipeater for regional message servers, each satellite is generic, which means that via one’s HT, that at any time serves to deliver the messages to all mobile handhelds within 1500 miles. The Regional Message Server ground station continuously transmits a stream of all message traffic. New messages are initially repeated more often than older messages on a decaying schedule. For example:

New messages are repeated every 2 minutes
- After 30 minutes every 3 minutes
- After 60 minutes every 4 minutes
- After 2 hours every 5 minutes
- After 4 hours every 6 minutes
- After 8 hours every 7 minutes
- After 16 hours every 8 minutes
- After 24 hours every 9 minutes

Thus, at 9600 baud and an average message length of 1K, over 500 messages per pass per satellite can be delivered. Yes, it makes the satellite less valuable over the oceans and most of the 3rd world, but those areas are aptly covered by the existing Pacsats that cannot deliver traffic to handhelds.
The Kenwood THD7 HT can be a handheld satellite transceiver with built-in 1200 and 9600 baud TNC's combined with keyboard and displays for position/status reporting and short messaging.

**DIGITAL MISSION:**

Just like the many worldwide commercial satellite pagers and hand-held phones, Amateur radio now has its own "satellite handheld" in the Kenwood TH-D7. Just one packet can contain everything you need to know about a station and it takes less than 0.3 seconds per station. This means that 10 times more users per pass will be able to participate on the digital transponder as on the voice channel! In addition, the digital packets containing the station's position and status and messages can be interlinked into the worldwide APRServe internet backbone allowing worldwide communications between these handheld users anywhere to anywhere. 

The digital mission using hand-held to handheld communications was recently demonstrated in an impromptu test during the first week in early June when more than 55 HT users easily communicated over 500 UI packets among 160 stations via the MIR digipeater. This presence of thousands of these shirt-pocket digital satellite communicators is an opportunity that should not be overlooked! Even conventional HT's can transmit APRS type position/status using only the match-box sized APRS Mic-Lite Mic-Encoder plugged into the mic jack.

The popularity and functionality of brief APRS UI type communications has been well demonstrated and is beyond the scope of this article. Readers can view the worldwide APRServe system live via TELNET to 199.227.85.221 port 23 at any time or check station positions via www.aprs.net. This system provides terrestrial HT coverage to over 90% of the US amateur population. (But less than 20% of the land mass and none of the oceans nor most foreign countries and Europe. Hence, the need to extend links via the digital builders channel).

**FREQUENCIES:**

One of the reasons for this builders channel concept is to make more efficient use of our existing spectrum and to allow for more orderly growth in the amateur satellite realm. There are many considerations in effectively designing a satellite link. First, 2 meters is, by an order of magnitude, the easiest band for handhelds, because the link budget is 9 dB easier and the doppler is negligible for existing FM radios. Conversely 70 cm has over 16 KHz of doppler and requires 9 times more power for the same performance. Thus, 70cm up and 2m downlink has the following advantages:

- 9 dB less power required on the satellite power system
- Omni spacecraft antennas require no attitude control
- No doppler tracking of downlink by users
- Compatible with all FM amateur radio equipment.
- Compatible with handheld TH-D7 packet HT

The UHF disadvantages are mitigated on the uplink as follows:

- Ground users can use more power, or gain antennas
- User can compensate for doppler OR
- Satellite receiver can have AFC OR
- Satellite can use a wideband IF to minimize doppler

![Figure](image.png)

This is an APRS screen capture after the third pass of MIR during the special APRS-MIR tests conducted on 11 March 1998. It demonstrated the potential of using an amateur satellite digipeater for relaying mobile position/status/messages.
The only downside of this arrangement is the difficulty on the Voice birds of filtering to avoid 3rd harmonic desense of the satellite UHF receiver by its 2 meter downlink. On the 2m 1200 baud digital channel, HT-to-HT operations will usually use the satellite as a single channel digipeater for UI frames thus providing the 9 dB and zero-doppler advantages to everyone with an HT as was demonstrated via MIR. Simplex digipeating is required since the thousands of satellite packet capable HT's contain TNC's that can only operate on one band at a time. To help spread out the uplink load, the mobiles with 10 dB more power can transmit on 70cm, where the satellite can use APC or a wideband receiver to mitigate the problem of high doppler.

Combining both uplink and downlink for the HT's on one channel is fortunately not a problem for the UI (APRS) application because dozens of ground stations are all linked by the internet. Thus only one ground station needs to receive the packet error free and it is distributed worldwide. Only 5 such ground stations would have a 99.99% chance of at least one of them hearing each packet and delivering it error free to the network even if their channel was more than 30% busy with local traffic.

In conclusion, I believe that establishing Builders Channels and, published Common Mission Objectives for mobile/HT worldwide satellite communications could greatly benefit the Amateur Satellite community. It would provide a mission target for schools, a much improved use of or sparse satellite bandwidth on 2 meters; and a constant source of satellites for a constellation of mobile communications amateur satellites. Further it defines a consistent user station class and power level for equal access by all, and promotes shorter practical protocols to allow more users brief access.
